# The Road Ahead...

- ① Measuring Unemployment
- ② Measuring Inflation
- ③ Real versus Nominal Interest Rates

# How to Measure Unemployment?

- ▶ Bureau of Census conducts Current Population Survey (CPS) to classify people as
  - ▶ employed (N): people who have job
  - ▶ unemployed (U): people who don't have job but are actively looking for one
  - ▶ not in labor force: neither, e.g. discouraged worker
- ▶ Bureau of Labor Statistics (BLS) uses CPS data to calculate
  - ▶ labor force ( $L$ ) =  $N + U$
  - ▶ unemployment rate ( $u$ ) =  $U / L \times 100\%$  (series U-3)
  - ▶ participation rate =  $L / \text{working-age population (civilian noninstitutional population)} \times 100\%$

# Working-Age Population

► Employment status, April 2017 (source: BLS)

# Broader Measure of Unemployment

- Series U-6 = U-3 + discouraged + part-time (source: BLS)
- Official U-3 is not exact measure of joblessness

# Types of Unemployment

- ▶ We identify three types of unemployment
  - ▶ frictional: temporary unemployment due to process of matching workers with jobs
  - ▶ structural: longer unemployment due to mismatch b/w worker's skills/attributes and job requirements
  - ▶ cyclical: unemployment due to business cycle recession
- ▶ When cyclical unemployment drops to zero
  - ▶ economy is at full employment
  - ▶ natural rate of unemployment ( $u_n$ )
  - ▶ general consensus for U.S.: b/w 4% and 5%
- ▶ Why unemployment rate never falls to zero?

# U.S. Unemployment Rate

- ▶ U.S. unemployment rate, 1950-2016 (source: BLS)
- ▶  $u$  rises during recessions and falls during expansions

# The Road Ahead...

- ① Measuring Unemployment
- ② Measuring Inflation
- ③ Real versus Nominal Interest Rates

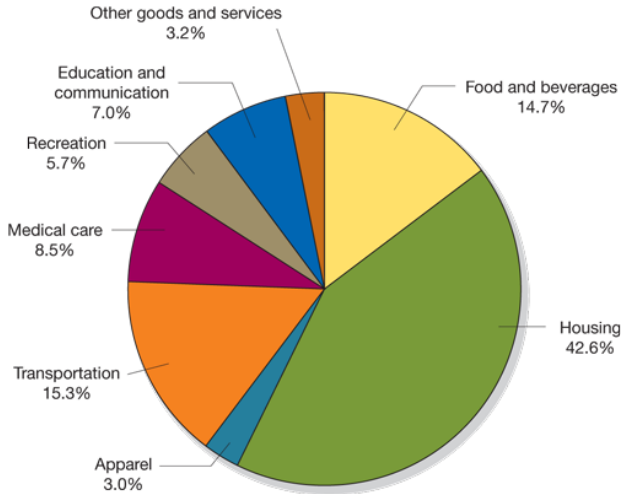

# How to Measure Inflation

- ▶ Three common measures of price level
  - ▶ GDP deflator (broadest)
  - ▶ consumer price index (CPI): price of basket of goods and services purchased by consumer (cost of living)
  - ▶ producer price index (PPI): price received by producers of goods and services at all stages of production
- ▶ Changes in PPI signifies future movements in CPI
- ▶ Inflation rate is percentage increase in price level

$$\pi_t = \frac{P_t - P_{t-1}}{P_{t-1}} \times 100\%$$

# CPI Market Basket

- ▶ CPI market basket, December 2016 (source: BLS)
- ▶ Housing, transportation, and food make up about 75%

## Calculating CPI

Product	1999		2020	2021
	Quantity	Price	Price	Price
Eye examinations	1	\$50	\$100	\$85
Pizzas	20	\$10	\$15	\$14
Books	20	\$25	\$25	\$27.5

- ▶ Assume base year is 1999
- ▶ Calculate CPI for year 2020 & 2021

$$\text{CPI} = \frac{\text{expenditures in current year}}{\text{expenditures in base year}} \times 100$$

$$\text{Answer: } P_{2020} = 120, \quad P_{2021} = 122$$

- ▶ 2021 inflation:  $\pi_{2021} = (122 - 120)/120 \times 100\% \approx 1.7\%$

## Purchasing Power

Year	Nominal Average Hourly Earnings	CPI (1982-1984=100)
2020	\$19.73	230
2021	\$20.14	233
2022	\$20.60	237

- ▶ Nominal variables are values in current-year dollars
- ▶ Calculate real values for years 2020-2022

$$\text{real variable} = \frac{\text{nominal variable}}{\text{current-year price index}} \times 100$$

Answer:  $W_{2020} = \$8.59$ ,  $W_{2021} = \$8.65$ ,  $W_{2022} = \$8.70$

- ▶ Compare growth rates in nominal and real values

# The Road Ahead...

- ① Measuring Unemployment
- ② Measuring Inflation
- ③ Real versus Nominal Interest Rates

# Real versus Nominal Interest Rates

- ▶ Interest rate is cost of borrowing funds
  - ▶ nominal interest rate ( $i$ ): expressed in terms of units of national currency; borrowing \$1 this year requires repaying  $\$(1+i)$  next year  
 $\Rightarrow$  this year's price of one dollar relative to next year
  - ▶ real interest rate ( $r$ ): expressed in terms of baskets of goods; borrowing one basket this year requires repaying  $(1+r)$  baskets next year  
 $\Rightarrow$  this year's price of one basket relative to next year
- ▶ Borrowers/lenders care about  $r$  rather than  $i$
- ▶ A useful (Fisher) relation

$$r_t \approx i_t - \pi_{t+1}^e \quad \text{for small } i_t \text{ and } \pi_{t+1}^e$$

# U.S. Interest Rates

- ▶  $i$  = interest rate on 3-month U.S. Treasury bills,  $\pi$  = percentage change in CPI (source: FRED)
- ▶ *ex-ante* versus *ex-post* real interest rates

# Readings & Exercises

- ▶ Readings

- ▶ HO: chapter 9

- ▶ BJ: lecture 1 (sec. 2, 3, 4), lecture 5 (sec. 1), 12 (sec. 1) (supplementary)

- ▶ Exercises

- ▶ HO: problem 1.7, 3.2, 4.6, 5.5, 6.6, D9.2

- ▶ Derive Fisher relation
